## THE UNIVERSITY OF MINNESOTA

Statistics 5401

October 17, 2005

Assignment Sheet No. 5

I apologize for posting this so late. I have included reading for the rest of the semester.

## **Midterm Examination**

I have rescheduled the same for Wednesday, October 26. It will be open book, open notes. Any needed tables other the normal,  $\chi^2$ , Student's t and F distributions in the text or Bonferronized probability points from the handout will be provided. It will cover everything up to and including single sample profile analysis, one-way MANOVA and MANOVA canonical variables.

## Reading (tentative)

Weeks of October 17-28: J&W, Sec. 6.8,7.7,7.8, 7.10; review Sec. 7.3 - 7.6 on univariate multiple regression Week of October 31 - November 4: J&W, Chapter 8 Week of November 7 - 11: J&W Sec 9.1 - 9.6 Week of November 14 - 18; J&W, Chapter 10 Week of November 21 - 23; J&W, Sec. 11.1 - 11.4 Week of November 28 - December 2; remainder of Chapter 11, Sec. 12.1-12.3 Week of December 5 - 9 J&W, Chapter 12

Written Assignment (due in class Monday, November 8)

1. Do J&W Ex. 6.24 (JWData5.txt data set T06\_13). Use the shortest simultaneous confidence limits that make sense. Also test in several ways the hypothesis that all periods have the same mean vector. Specifically, use Bonferronized F-tests, Roy's maximum relative eigenvalue test, Hotelling's generalized  $T_0^2$  and Pillai's V test. Use  $\alpha = .05$ . What do the coefficients of the canonical variables tell you about how skull measurements differed between periods?

2. Do J&W Ex. 6.25 (JWData5.txt data set T11\_07). Use the shortest simultaneous confidence limits that make sense.

3. In a study of the effects of whole-body radiation, 24 rats were subjected to radiation, 12 at level 500 r. and 12 at level 600 r. In each treatment group there were 3 rats in each of the following 4 classifications: young male, adult male, young female and adult female.

Thus the experiment was a  $2^3$  factorial experiment with factors A = radiation level, B = age, and C = sex. Weight changes  $y_1$ ,  $y_2$ ,  $y_3$ , and  $y_4$  were recorded 1, 3, 6, and 7 days after the irradiation. In addition, the initial weight u was recorded as a covariate but *should be ignored in this assignment*. On the next page is a listing of file radfact.txt which contains a MacAnova array made up of five 5 by 5 hypothesis or error matrices,  $H^A$ ,  $H^B$ ,  $H^C$ ,  $H^{(4)}$ , and E. There is a link to radfact.txt on http://www.stat.umn.edu/~kb/classes/5401/datafiles.html.

 $H^A$ ,  $H^B$ , and  $H^C$  are *main effect* hypothesis matrices.

Matrix  $H^{(4)} = H^{AB} + H^{AC} + H^{BC} + H^{ABC}$  is the sum of hypothesis matrices that might be used to test the indicated interactions but which are not available separately, can be used to test the hypothesis that there are no two-way or threeway *interactions* among the 3 factors. The degrees of freedom associated with  $H^{(4)}$  is the sum of the degrees of freedom associated with its component matrices.

Matrix *E* is the error matrix from the complete factorial model.

```
Cmd> sscp <- read("","sscp") # read from radfact.txt</pre>

Cmd> print(sscp,format:"9.2f") # array has labels
sscp:

Let  $H_{yy}^{A}$ ,  $H_{yy}^{B}$ ,  $H_{yy}^{C}$ ,  $H_{yy}^{(4)}$ , and  $E_{yy}$ , be the *lower right hand* 4 by 4 submatrices of these matrices, that is omitting the row and column associated with u.

The parts of the matrices having to do with *y* can be extracted as follows. In every sub array (matrix) we omit the first row and column (initial weight).

```
Cmd> ha <- matrix(sscp[1,-1,-1])
Cmd> hb <- matrix(sscp[2,-1,-1])
Cmd> hc <- matrix(sscp[3,-1,-1])
Cmd> h4 <- matrix(sscp[4,-1,-1])
Cmd> e <- matrix(sscp[5,-1,-1])</pre>
```

The use of matrix() without a dimension, turns its argument into a pure matrix with only two dimensions. Without it, matrices[i,-1,-1] would be 1 by 4 by 4 arrays. These would be correctly handled by functions like solve() or releigen() but the extra dimension might be confusing.

Use  $H_{yy}^{A}$ ,  $H_{yy}^{B}$ ,  $H_{yy}^{C}$ ,  $H_{yy}^{(4)}$ , and  $E_{yy}$  in the following:

(a) Test for the presence of interaction by comparing  $H_{yy}^{(4)}$  with  $E_{yy}$  using both the Wilks test statistic and the largest root test.

(b) Test for age and sex main effects using the Wilks statistic and in both cases obtain the *coefficients* used to compute the most important canonical variate.
